Surgery

Standard Edit

For cementless total hip arthroplasty (THA), can be performed using a large variety of femoral components with a large variety of designs have been developed. The Anatomic Fiber Metal plus stem (Zimmer) is one of the an anatomically designed femoral components that to can be inserted implanted without cement. The concept of this stem was is designed to achieve stable fixation throughby metaphyseal fit and fill. It has a configuration matching that of a the medullary canal of a normal femur, and circumferential the circumference of its fiber mesh coating on the proximal one-third is coated with fiber mesh. The neck of the stem has an anteversion of twelve–12 degrees. The press-fit and outcomes of THA performed using a press-fit femoral this stem were have been reported to be good for the primary osteoarthritis in selected Caucasian patients. However, but there were are a few reports on the outcomes of THA using this stem this procedure in Japanese patients. Since The majority of the most Japanese patients with hip osteoarthritis are have dysplastic hips in Japanese patients. Therefore, the results of this procedure in these patients might be different differ from those in Caucasian patients.

Therefore, We we studied the outcomes of cementless total hip arthroplasty (THA) performed using the Anatomic Fiber Metal plus stem in Japanese patients and examined the possible effects of metaphyseal fit on the outcomes.
